# Package 'dbplyr'

February 3, 2021

```
Type Package
Title A 'dplyr' Back End for Databases
Version 2.1.0
Description A 'dplyr' back end for databases that allows you to
      work with remote database tables as if they are in-memory data frames.
      Basic features works with any database that has a 'DBI' back end; more
      advanced features require 'SQL' translation to be provided by the
      package author.

arrange.tbl\_lazy 5

# **Description**

This is an method for the dplyr arrange() generic. It generates the ORDER BY clause of the SQL query. It also affects the window\_order() of windowed expressions in mutate.tbl\_lazy().

Note that ORDER BY clauses can not generally appear in subqueries, which means that you should arrange() as late as possible in your pipelines.

# Usage

```
## S3 method for class 'tbl_lazy'
arrange(.data, ..., .by_group = FALSE)
```

### **Arguments**

.data	A lazy data frame backed by a database query.
•••	<pre><data-masking> Variables, or functions or variables. Use desc() to sort a variable in descending order.</data-masking></pre>
.by_group	If TRUE, will sort first by grouping variable. Applies to grouped data frames only.

#### Value

Another  $tbl_{lazy}$ . Use  $show_{query}$ () to see the generated query, and use collect() to execute the query and return data to R.

# Missing values

Unlike R, most databases sorts NA (NULLs) at the front. You can can override this behaviour by explicitly sorting on is.na(x).

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(a = c(3, 4, 1, 2), b = c(5, 1, 2, NA))
db %>% arrange(a) %>% show_query()

# Note that NAs are sorted first
db %>% arrange(b)
# override by sorting on is.na() first
db %>% arrange(is.na(b), b)
```

6 backend-hana

backend-access

Backend: MS Access

# **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- SELECT uses TOP, not LIMIT
- Non-standard types and mathematical functions
- String concatenation uses &
- No ANALYZE equivalent
- TRUE and FALSE converted to 1 and 0

Use simulate\_access() with lazy\_frame() to see simulated SQL without converting to live access database.

# Usage

```
simulate_access()
```

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)
lf <- lazy_frame(x = 1, y = 2, z = "a", con = simulate_access())
lf %>% head()
lf %>% mutate(y = as.numeric(y), z = sqrt(x^2 + 10))
lf %>% mutate(a = paste0(z, " times"))
```

backend-hana

Backend: SAP HANA

# Description

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- Temporary tables get # prefix and use LOCAL TEMPORARY COLUMN.
- No table analysis performed in copy\_to().
- paste() uses ||
- Note that you can't create new boolean columns from logical expressions; you need to wrap with explicit ifelse: ifelse(x > y,TRUE,FALSE).

Use simulate\_hana() with lazy\_frame() to see simulated SQL without converting to live access database.

```
simulate_hana()
```

backend-hive 7

#### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_hana())

lf %>% transmute(x = paste0(z, " times"))
```

backend-hive

Backend: Hive

#### **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are a scattering of custom translations provided by users.

Use simulate\_hive() with lazy\_frame() to see simulated SQL without converting to live access database.

### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, d = 2, c = "z", con = simulate_hive())

lf %>% transmute(x = cot(b))

lf %>% transmute(x = bitwShiftL(c, 1L))

lf %>% transmute(x = str_replace_all(z, "a", "b"))

lf %>% summarise(x = median(d, na.rm = TRUE))

lf %>% summarise(x = var(c, na.rm = TRUE))
```

backend-impala

Backend: Impala

# **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are a scattering of custom translations provided by users, mostly focussed on bitwise operations.

Use simulate\_impala() with lazy\_frame() to see simulated SQL without converting to live access database.

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_impala())

lf %>% transmute(X = bitwNot(bitwOr(b, c)))
```

8 backend-mssql

backend-mssql

Backend: SQL server

### **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- SELECT uses TOP not LIMIT
- Automatically prefixes # to create temporary tables. Add the prefix yourself to avoid the message.
- String basics: paste(), substr(), nchar()
- Custom types for as.\* functions
- Lubridate extraction functions, year(), month(), day() etc
- Semi-automated bit <-> boolean translation (see below)

Use simulate\_mssql() with lazy\_frame() to see simulated SQL without converting to live access database.

#### **Arguments**

version

Version of MS SQL to simulate. Currently only, difference is that 15.0 and above will use TRY\_CAST() instead of CAST().

### Bit vs boolean

SQL server uses two incompatible types to represent TRUE and FALSE values:

- The BOOLEAN type is the result of logical comparisons (e.g. x > y) and can be used WHERE but not to create new columns in SELECT. https://docs.microsoft.com/en-us/sql/t-sql/language-elements/comparison-operators-transact-sql
- The BIT type is a special type of numeric column used to store TRUE and FALSE values, but can't be used in WHERE clauses. https://docs.microsoft.com/en-us/sql/t-sql/data-types/bit-transact-sql?view=sql-server-ver15

dbplyr does its best to automatically create the correct type when needed, but can't do it 100% correctly because it does not have a full type inference system. This means that you many need to manually do conversions from time to time.

- To convert from bit to boolean use x == 1
- To convert from boolean to bit use as.logical(if(x, 0, 1))

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_mssql())

lf %>% head()

lf %>% transmute(x = paste(b, c, d))

# Can use boolean as is:
```

backend-mysql 9

```
lf %>% filter(c > d)
# Need to convert from boolean to bit:
lf %>% transmute(x = c > d)
# Can use boolean as is:
lf %>% transmute(x = ifelse(c > d, "c", "d"))
```

backend-mysql

Backend: MySQL/MariaDB

# Description

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- paste() uses CONCAT\_WS()
- String translations for str\_detect(), str\_locate(), and str\_replace\_all()
- · Clear error message for unsupported full joins

Use simulate\_mysql() with lazy\_frame() to see simulated SQL without converting to live access database.

# Usage

```
simulate_mysql()
```

# Examples

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_mysql())
lf %>% transmute(x = paste0(z, " times"))
```

backend-odbc

Backend: ODBC

# **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are minor translations for common data types.

Use simulate\_odbc() with lazy\_frame() to see simulated SQL without converting to live access database.

```
simulate_odbc()
```

10 backend-postgres

#### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, d = 2, c = "z", con = simulate_odbc())

lf %>% transmute(x = as.numeric(b))

lf %>% transmute(x = as.integer(b))

lf %>% transmute(x = as.character(b))
```

backend-oracle

Backend: Oracle

### **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- · Use FETCH FIRST instead of LIMIT
- Custom types
- paste() uses ||
- Custom subquery generation (no AS)
- setdiff() uses MINUS instead of EXCEPT

Use simulate\_oracle() with lazy\_frame() to see simulated SQL without converting to live access database.

# Usage

```
simulate_oracle()
```

### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_oracle())

lf %>% transmute(x = paste0(c, " times"))

lf %>% setdiff(lf)
```

backend-postgres

Backend: PostgreSQL

### **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- Many stringr functions
- · lubridate date-time extraction functions
- · More standard statistical summaries

Use simulate\_postgres() with lazy\_frame() to see simulated SQL without converting to live access database.

backend-redshift 11

#### Usage

```
simulate_postgres()
```

#### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_postgres())

lf %>% summarise(x = sd(b, na.rm = TRUE))

lf %>% summarise(y = cor(b, c), y = cov(b, c))
```

backend-redshift

Backend: Redshift

### **Description**

Base translations come from PostgreSQL backend. There are generally few differences, apart from string manipulation.

Use simulate\_redshift() with lazy\_frame() to see simulated SQL without converting to live access database.

# Usage

```
simulate_redshift()
```

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_redshift())

lf %>% transmute(x = paste(c, " times"))

lf %>% transmute(x = substr(c, 2, 3))

lf %>% transmute(x = str_replace_all(c, "a", "z"))
```

 ${\it backend-sqlite}$ 

Backend: SQLite

# **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- Uses non-standard LOG() function
- Date-time extraction functions from lubridate
- · Custom median translation
- Right and full joins are simulated using left joins

Use simulate\_sqlite() with lazy\_frame() to see simulated SQL without converting to live access database.

12 collapse.tbl\_sql

#### Usage

```
simulate_sqlite()
```

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_sqlite())

lf %>% transmute(x = paste(c, " times"))

lf %>% transmute(x = log(b), y = log(b, base = 2))
```

backend-teradata

Backend: Teradata

# **Description**

See vignette("translate-function") and vignette("translate-verb") for details of overall translation technology. Key differences for this backend are:

- · Uses TOP instead of LIMIT
- Selection of user supplied translations

Use simulate\_teradata() with lazy\_frame() to see simulated SQL without converting to live access database.

### Usage

```
simulate_teradata()
```

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

lf <- lazy_frame(a = TRUE, b = 1, c = 2, d = "z", con = simulate_teradata())

lf %>% head()
```

collapse.tbl\_sql

Compute results of a query

# **Description**

These are methods for the dplyr generics collapse(), compute(), and collect(). collapse() creates a subquery, compute() stores the results in a remote table, and collect() executes the query and downloads the data into R.

complete.tbl\_lazy 13

#### Usage

```
## S3 method for class 'tbl_sql'
collapse(x, ...)

## S3 method for class 'tbl_sql'
compute(
    x,
    name = unique_table_name(),
    temporary = TRUE,
    unique_indexes = list(),
    indexes = list(),
    analyze = TRUE,
    ...
)

## S3 method for class 'tbl_sql'
collect(x, ..., n = Inf, warn_incomplete = TRUE)
```

# **Arguments**

x A lazy data frame backed by a database query.

... other parameters passed to methods.

name Table name in remote database.

temporary Should the table be temporary (TRUE, the default) or persistent (FALSE')?

unique\_indexes a list of character vectors. Each element of the list will create a new unique

index over the specified column(s). Duplicate rows will result in failure.

indexes a list of character vectors. Each element of the list will create a new index.

analyze if TRUE (the default), will automatically ANALYZE the new table so that the

query optimiser has useful information.

n Number of rows to fetch. Defaults to Inf, meaning all rows.

warn\_incomplete

Warn if n is less than the number of result rows?

# **Examples**

```
library(dplyr, warn.conflicts = FALSE) 
 db <- memdb_frame(a = c(3, 4, 1, 2), b = c(5, 1, 2, NA)) 
 db %>% filter(a <= 2) %>% collect()
```

complete.tbl\_lazy

Complete a SQL table with missing combinations of data

### **Description**

Turns implicit missing values into explicit missing values. This is a method for the tidyr::complete() generic.

14 copy\_to.src\_sql

#### Usage

```
complete.tbl_lazy(data, ..., fill = list())
```

#### **Arguments**

A lazy data frame backed by a database query.

Specification of columns to expand. See tidyr::expand for more details.

A named list that for each variable supplies a single value to use instead of NA for missing combinations.

#### Value

Another tbl\_lazy. Use show\_query() to see the generated query, and use collect() to execute the query and return data to R.

# **Examples**

```
if (require("tidyr", quietly = TRUE)) {
    df <- memdb_frame(
        group = c(1:2, 1),
        item_id = c(1:2, 2),
        item_name = c("a", "b", "b"),
        value1 = 1:3,
        value2 = 4:6
    )

    df %>% complete(group, nesting(item_id, item_name))

# You can also choose to fill in missing values
    df %>% complete(group, nesting(item_id, item_name), fill = list(value1 = 0))
}
```

copy\_to.src\_sql

Copy a local data frame to a remote database

#### **Description**

This is an implementation of the dplyr copy\_to() generic and it mostly a wrapper around DBI::dbWriteTable().

It is useful for copying small amounts of data to a database for examples, experiments, and joins. By default, it creates temporary tables which are only visible within the current connection to the database.

```
## S3 method for class 'src_sql'
copy_to(
  dest,
  df,
  name = deparse(substitute(df)),
  overwrite = FALSE,
  types = NULL,
```

copy\_to.src\_sql 15

```
temporary = TRUE,
unique_indexes = NULL,
indexes = NULL,
analyze = TRUE,
...,
in_transaction = TRUE
```

#### **Arguments**

dest remote data source

df A local data frame, a tbl\_sql from same source, or a tbl\_sql from another

source. If from another source, all data must transition through R in one pass,

so it is only suitable for transferring small amounts of data.

name for new remote table.

overwrite If TRUE, will overwrite an existing table with name name. If FALSE, will throw

an error if name already exists.

types a character vector giving variable types to use for the columns. See https:

//www.sqlite.org/datatype3.html for available types.

temporary if TRUE, will create a temporary table that is local to this connection and will be

automatically deleted when the connection expires

unique\_indexes a list of character vectors. Each element of the list will create a new unique

index over the specified column(s). Duplicate rows will result in failure.

indexes a list of character vectors. Each element of the list will create a new index.

analyze if TRUE (the default), will automatically ANALYZE the new table so that the

query optimiser has useful information.

... other parameters passed to methods.

in\_transaction Should the table creation be wrapped in a transaction? This typically makes

things faster, but you may want to suppress if the database doesn't support transactions, or you're wrapping in a transaction higher up (and your database doesn't

support nested transactions.)

#### Value

Another  $tbl_{lazy}$ . Use  $show_{query}()$  to see the generated query, and use collect() to execute the query and return data to R.

```
library(dplyr, warn.conflicts = FALSE)

df <- data.frame(x = 1:5, y = letters[5:1])
db <- copy_to(src_memdb(), df)
db

df2 <- data.frame(y = c("a", "d"), fruit = c("apple", "date"))
# copy_to() is called automatically if you set copy = TRUE
# in the join functions
db %>% left_join(df2, copy = TRUE)
```

16 dbplyr-slice

count.tbl\_lazy

Count observations by group

#### **Description**

These are methods for the dplyr count() and tally() generics. They wrap up group\_by.tbl\_lazy(), summarise.tbl\_lazy() and, optionally, arrange.tbl\_lazy().

# Usage

```
## S3 method for class 'tbl_lazy'
count(x, ..., wt = NULL, sort = FALSE, name = NULL)
## S3 method for class 'tbl_lazy'
tally(x, wt = NULL, sort = FALSE, name = NULL)
```

#### **Arguments**

X	A data frame, data frame extension (e.g. a tibble), or	a lazy data frame (e.g.
	from dbplyr or dtplyr).	
	<pre><data-macking> Variables or functions or variables</data-macking></pre>	Use desc() to sort a

<data-masking> Variables, or functions or variables. Use desc() to sort a variable in descending order.

<data-masking> Frequency weights. Can be NULL or a variable: wt

• If NULL (the default), counts the number of rows in each group.

• If a variable, computes sum(wt) for each group.

sort If TRUE, will show the largest groups at the top. The name of the new column in the output. name

If omitted, it will default to n. If there's already a column called n, it will error,

and require you to specify the name.

### **Examples**

```
library(dplyr, warn.conflicts = FALSE)
db \leftarrow memdb_frame(g = c(1, 1, 1, 2, 2), x = c(4, 3, 6, 9, 2))
db %>% count(g) %>% show_query()
db %>% count(g, wt = x) %>% show_query()
db %>% count(g, wt = x, sort = TRUE) %>% show_query()
```

dbplyr-slice

Subset rows using their positions

#### **Description**

These are methods for the dplyr generics slice\_min(), slice\_max(), and slice\_sample(). They are translated to SQL using filter() and window functions (ROWNUMBER, MIN\_RANK, or CUME\_DIST depending on arguments). slice(), slice\_head(), and slice\_tail() are not supported since database tables have no intrinsic order.

If data is grouped, the operation will be performed on each group so that (e.g.) slice\_min(db,x,n = 3) will select the three rows with the smallest value of x in each group.

dbplyr\_uncount 17

#### Usage

```
## S3 method for class 'tbl_lazy'
slice_min(.data, order_by, ..., n, prop, with_ties = TRUE)
## S3 method for class 'tbl_lazy'
slice_max(.data, order_by, ..., n, prop, with_ties = TRUE)
## S3 method for class 'tbl_lazy'
slice_sample(.data, ..., n, prop, weight_by = NULL, replace = FALSE)
```

# **Arguments**

.data A lazy data frame backed by a database query.
... Variable or function of variables to order by.
... Not used.
n, prop Provide either n, the number of rows, or prop, the proportion of rows to select. If neither are supplied, n = 1 will be used.

If n is greater than the number of rows in the group (or prop > 1), the result will be silently truncated to the group size. If the proportion of a group size is not an integer, it is rounded down.
with\_ties Should ties be kept together? The default, TRUE, may return more rows than you request. Use FALSE to ignore ties, and return the first n rows.

Not supported for database backends.

# **Examples**

weight\_by, replace

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = 1:3, y = c(1, 1, 2))
 db %>% slice_min(x) %>% show_query()
 db %>% slice_max(x) %>% show_query()
 db %>% slice_sample() %>% show_query()

db %>% group_by(y) %>% slice_min(x) %>% show_query()

# By default, ties are includes so you may get more rows # than you expect
 db %>% slice_min(y, n = 1)
 db %>% slice_min(y, n = 1, with_ties = FALSE)

# Non-integer group sizes are rounded down
 db %>% slice_min(x, prop = 0.5)
```

dbplyr\_uncount

"Uncount" a database table

### **Description**

This is a method for the tidyr uncount() generic. It uses a temporary table, so your database user needs permissions to create one.

18 distinct.tbl\_lazy

### Usage

```
dbplyr_uncount(data, weights, .remove = TRUE, .id = NULL)
```

### **Arguments**

data

A lazy data frame backed by a database query.

Weights

A vector of weights. Evaluated in the context of data; supports quasiquotation.

If TRUE, and weights is the name of a column in data, then this column is removed.

Supply a string to create a new variable which gives a unique identifier for each

created row.

# **Examples**

```
df <- memdb_frame(x = c("a", "b"), n = c(1, 2))
dbplyr_uncount(df, n)
dbplyr_uncount(df, n, .id = "id")

# You can also use constants
dbplyr_uncount(df, 2)

# Or expressions
dbplyr_uncount(df, 2 / n)</pre>
```

distinct.tbl\_lazy

Subset distinct/unique rows

# **Description**

This is a method for the dplyr distinct() generic. It adds the DISTINCT clause to the SQL query.

### Usage

```
## S3 method for class 'tbl_lazy'
distinct(.data, ..., .keep_all = FALSE)
```

#### **Arguments**

.data A lazy data frame backed by a database query.
... <data-masking> Variables, or functions or variables. Use desc() to sort a variable in descending order.
.keep\_all If TRUE, keep all variables in .data. If a combination of ... is not distinct, this keeps the first row of values.

#### Value

Another  $tbl_{lazy}$ . Use  $show_{query}()$  to see the generated query, and use collect() to execute the query and return data to R.

do.tbl\_sql 19

#### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = c(1, 1, 2, 2), y = c(1, 2, 1, 1))
db %>% distinct() %>% show_query()
db %>% distinct(x) %>% show_query()
```

do.tbl\_sql

Perform arbitrary computation on remote backend

#### **Description**

Perform arbitrary computation on remote backend

# Usage

```
## S3 method for class 'tbl_sql'
do(.data, ..., .chunk_size = 10000L)
```

# Arguments

.data a tbl

Expressions to apply to each group. If named, results will be stored in a new column. If unnamed, should return a data frame. You can use . to refer to the

current group. You can not mix named and unnamed arguments.

.chunk\_size The size of each chunk to pull into R. If this number is too big, the process will

be slow because R has to allocate and free a lot of memory. If it's too small, it

will be slow, because of the overhead of talking to the database.

escape

Escape/quote a string.

# Description

escape() requires you to provide a database connection to control the details of escaping. escape\_ansi() uses the SQL 92 ANSI standard.

```
escape(x, parens = NA, collapse = " ", con = NULL)
escape_ansi(x, parens = NA, collapse = "")
sql_vector(x, parens = NA, collapse = " ", con = NULL)
```

20 expand.tbl\_lazy

### **Arguments**

Х

An object to escape. Existing sql vectors will be left as is, character vectors are escaped with single quotes, numeric vectors have trailing .0 added if they're whole numbers, identifiers are escaped with double quotes.

parens, collapse

Controls behaviour when multiple values are supplied. parens should be a logical flag, or if NA, will wrap in parens if length > 1.

Default behaviour: lists are always wrapped in parens and separated by commas, identifiers are separated by commas and never wrapped, atomic vectors are separated by spaces and wrapped in parens if needed.

con

Database connection.

### **Examples**

```
# Doubles vs. integers
escape_ansi(1:5)
escape_ansi(c(1, 5.4))

# String vs known sql vs. sql identifier
escape_ansi("X")
escape_ansi(sql("X"))
escape_ansi(ident("X"))

# Escaping is idempotent
escape_ansi("X")
escape_ansi(escape_ansi("X"))
escape_ansi(escape_ansi(escape_ansi("X")))
```

expand.tbl\_lazy

Expand SQL tables to include all possible combinations of values

# Description

This is a method for the tidyr::expand generics. It doesn't sort the result explicitly, so the order might be different to what expand() returns for data frames.

#### Usage

```
expand.tbl_lazy(data, ..., .name_repair = "check_unique")
```

### **Arguments**

data

A lazy data frame backed by a database query.

. . .

Specification of columns to expand. See tidyr::expand for more details.

.name\_repair

Treatment of problematic column names:

- "minimal": No name repair or checks, beyond basic existence,
- "unique": Make sure names are unique and not empty,
- "check\_unique": (default value), no name repair, but check they are unique,
- "universal": Make the names unique and syntactic

fill.tbl\_lazy 21

> • a function: apply custom name repair (e.g., .name\_repair = make.names for names in the style of base R).

• A purrr-style anonymous function, see rlang::as\_function()

This argument is passed on as repair to vctrs::vec\_as\_names(). See there for more details on these terms and the strategies used to enforce them.

# Value

Another tbl\_lazy. Use show\_query() to see the generated query, and use collect() to execute the query and return data to R.

#### **Examples**

```
if (require("tidyr", quietly = TRUE)) {
 fruits <- memdb_frame(</pre>
   type = c("apple", "orange", "apple", "orange", "orange", "orange"),
   year = c(2010, 2010, 2012, 2010, 2010, 2012),
   size = c("XS", "S", "M", "S", "S", "M"),
   weights = rnorm(6)
 )
 # All possible combinations -----
 fruits %>% expand(type)
 fruits %>% expand(type, size)
 # Only combinations that already appear in the data ------
 fruits %>% expand(nesting(type, size))
}
```

fill.tbl\_lazy

Fill in missing values with previous or next value

# **Description**

Fill in missing values with previous or next value

# Usage

```
fill.tbl_lazy(.data, ..., .direction = c("down", "up"))
```

#### **Arguments**

.data A lazy data frame backed by a database query.

Columns to fill.

.direction Direction in which to fill missing values. Currently either "down" (the default) or "up". Note that "up" does not work when .data is sorted by non-numeric

columns. As a workaround revert the order yourself beforehand; for example

replace arrange(x, desc(y)) by arrange(desc(x), y).

22 filter.tbl\_lazy

#### **Examples**

```
squirrels <- tibble::tribble(</pre>
  ~group, ~name, ~role,
                                     ~n_squirrels, ~ n_squirrels2,
         "Sam", "Observer",
"Mara", "Scorekeeper",
                                    NA,
                                                         1,
                                    8,
 1,
                                                         NA,
                    "Observer",
       "Jesse",
  1,
                                    NA,
                                                         NA,
          "Tom",
                     "Observer",
                                    NA,
                                                         4,
  1,
        "Mike",
  2,
                    "Observer",
                                    NA,
                                                         NA,
     "Rachael", "Observer", "Sydekea", "Scorekeeper",
  2,
                                    NA,
                                                         6,
  2,
                                    14,
                                                         NA,
  2, "Gabriela",
                    "Observer",
                                                         NA,
                     "Observer",
      "Derrick",
  3,
                                    NA,
                                                         NA,
        "Kara", "Scorekeeper",
  3,
                                    9,
                                                         10,
        "Emily",
                     "Observer",
  3,
                                                         NA,
                                    NA,
  3, "Danielle",
                     "Observer",
                                    NA,
                                                         NA
)
squirrels$id <- 1:12
if (require("tidyr", quietly = TRUE)) {
  tbl_memdb(squirrels) %>%
    window_order(id) %>%
    tidyr::fill(
      n_squirrels,
      n_squirrels2,
    )
}
```

filter.tbl\_lazy

Subset rows using column values

### **Description**

This is a method for the dplyr filter() generic. It generates the WHERE clause of the SQL query.

# Usage

```
## S3 method for class 'tbl_lazy'
filter(.data, ..., .preserve = FALSE)
```

# **Arguments**

```
    .data A lazy data frame backed by a database query.
    ... <a href="data-masking">data-masking</a> Variables, or functions or variables. Use desc() to sort a variable in descending order.
    .preserve Not supported by this method.
```

### Value

Another  $tbl_{lazy}$ . Use  $show_{query}()$  to see the generated query, and use collect() to execute the query and return data to R.

group\_by.tbl\_lazy 23

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = c(2, NA, 5, NA, 10), y = 1:5)
db %>% filter(x < 5) %>% show_query()
db %>% filter(is.na(x)) %>% show_query()
```

group\_by.tbl\_lazy

Group by one or more variables

# Description

This is a method for the dplyr group\_by() generic. It is translated to the GROUP BY clause of the SQL query when used with summarise() and to the PARTITION BY clause of window functions when used with mutate().

# Usage

```
## S3 method for class 'tbl_lazy'
group_by(.data, ..., .add = FALSE, add = NULL, .drop = TRUE)
```

# **Arguments**

.data	A lazy data frame backed by a database query.
•••	<pre><data-masking> Variables, or functions or variables. Use desc() to sort a variable in descending order.</data-masking></pre>
. add	When FALSE, the default, group_by() will override existing groups. To add to the existing groups, use .add = TRUE.
	This argument was previously called add, but that prevented creating a new grouping variable called add, and conflicts with our naming conventions.
add	Deprecated. Please use . add instead.
.drop	Not supported by this method.

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(g = c(1, 1, 1, 2, 2), x = c(4, 3, 6, 9, 2))
db %>%
    group_by(g) %>%
    summarise(n()) %>%
    show_query()

db %>%
    group_by(g) %>%
    mutate(x2 = x / sum(x, na.rm = TRUE)) %>%
    show_query()
```

24 ident

head.tbl\_lazy

Subset the first rows

### **Description**

This is a method for the head() generic. It is usually translated to the LIMIT clause of the SQL query. Because LIMIT is not an official part of the SQL specification, some database use other clauses like TOP or FETCH ROWS.

Note that databases don't really have a sense of row order, so what "first" means is subject to interpretation. Most databases will respect ordering performed with arrange(), but it's not guaranteed. tail() is not supported at all because the situation is even murkier for the "last" rows.

# Usage

```
## S3 method for class 'tbl_lazy'
head(x, n = 6L, ...)
```

# Arguments

x A lazy data frame backed by a database query.

n Number of rows to return

... Not used.

### Value

Another  $tbl_{lazy}$ . Use  $show_{query}$ () to see the generated query, and use collect() to execute the query and return data to R.

### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = 1:100)
  db %>% head() %>% show_query()

# Pretend we have data in a SQL server database
  db2 <- lazy_frame(x = 1:100, con = simulate_mssql())
  db2 %>% head() %>% show_query()
```

ident

Flag a character vector as SQL identifiers

# Description

ident() takes unquoted strings and flags them as identifiers. ident\_q() assumes its input has already been quoted, and ensures it does not get quoted again. This is currently used only for for schema.table.

intersect.tbl\_lazy 25

### Usage

```
ident(...)
is.ident(x)
```

#### **Arguments**

```
A character vector, or name-value pairsAn object
```

# **Examples**

```
# SQL92 quotes strings with '
escape_ansi("x")

# And identifiers with "
ident("x")
escape_ansi(ident("x"))

# You can supply multiple inputs
ident(a = "x", b = "y")
ident_q(a = "x", b = "y")
```

intersect.tbl\_lazy SQL set operations

# Description

These are methods for the dplyr generics dplyr::intersect(), dplyr::union(), and dplyr::setdiff(). They are translated to INTERSECT, UNION, and EXCEPT respectively.

# Usage

```
## S3 method for class 'tbl_lazy'
intersect(x, y, copy = FALSE, ..., all = FALSE)
## S3 method for class 'tbl_lazy'
union(x, y, copy = FALSE, ..., all = FALSE)
## S3 method for class 'tbl_lazy'
union_all(x, y, copy = FALSE, ...)
## S3 method for class 'tbl_lazy'
setdiff(x, y, copy = FALSE, ..., all = FALSE)
```

# **Arguments**

```
x A pair of lazy data frames backed by database queries.
```

y A pair of lazy data frames backed by database queries.

in\_schema

сору	If x and y are not from the same data source, and copy is TRUE, then y will be copied into a temporary table in same database as x. *_join() will automatically run ANALYZE on the created table in the hope that this will make you queries as efficient as possible by giving more data to the query planner.
	This allows you to join tables across srcs, but it's potentially expensive operation so you must opt into it.
	Not currently used; provided for future extensions.
all	If TRUE, includes all matches in output, not just unique rows.

in\_schema

Refer to a table in a schema

# Description

Refer to a table in a schema

# Usage

```
in_schema(schema, table)
```

# Arguments

schema, table

Names of schema and table. These will be automatically quoted; use sql() to pass a raw name that won't get quoted.

```
in_schema("my_schema", "my_table")
# eliminate quotes
in_schema(sql("my_schema"), sql("my_table"))
# Example using schemas with SQLite
con <- DBI::dbConnect(RSQLite::SQLite(), ":memory:")
# Add auxilary schema
tmp <- tempfile()
DBI::dbExecute(con, paste0("ATTACH '", tmp, "' AS aux"))
library(dplyr, warn.conflicts = FALSE)
copy_to(con, iris, "df", temporary = FALSE)
copy_to(con, mtcars, in_schema("aux", "df"), temporary = FALSE)
con %>% tbl("df")
con %>% tbl(in_schema("aux", "df"))
```

join.tbl\_sql 27

join.tbl\_sql

Join SQL tables

#### **Description**

These are methods for the dplyr join generics. They are translated to the following SQL queries:

```
• inner_join(x,y): SELECT * FROM x JOIN y ON x.a = y.a
```

- left\_join(x,y): SELECT \* FROM x LEFT JOIN y ON x.a = y.a
- right\_join(x,y): SELECT \* FROM x RIGHT JOIN y ON x.a = y.a
- full\_join(x,y): SELECT \* FROM x FULL JOIN y ON x.a = y.a
- semi\_join(x,y): SELECT \* FROM x WHERE EXISTS (SELECT 1 FROM y WHERE x.a = y.a)
- anti\_join(x,y): SELECT \* FROM x WHERE NOT EXISTS (SELECT 1 FROM y WHERE x.a = y.a)

```
## S3 method for class 'tbl_lazy'
inner_join(
  Х,
  у,
  by = NULL,
  copy = FALSE,
  suffix = NULL,
  auto_index = FALSE,
  sql_on = NULL,
  na_matches = c("never", "na")
## S3 method for class 'tbl_lazy'
left_join(
  Х,
  у,
  by = NULL,
  copy = FALSE,
  suffix = NULL,
  auto_index = FALSE,
  sql_on = NULL,
  na_matches = c("never", "na")
## S3 method for class 'tbl_lazy'
right_join(
  Х,
  у,
  by = NULL,
  copy = FALSE,
  suffix = NULL,
  auto_index = FALSE,
```

28 join.tbl\_sql

```
. . . ,
  sql_on = NULL,
  na_matches = c("never", "na")
)
## S3 method for class 'tbl_lazy'
full_join(
  х,
  у,
  by = NULL,
  copy = FALSE,
  suffix = NULL,
  auto_index = FALSE,
  sql_on = NULL,
  na_matches = c("never", "na")
## S3 method for class 'tbl_lazy'
semi_join(
  х,
  by = NULL,
  copy = FALSE,
  auto_index = FALSE,
  sql_on = NULL,
  na_matches = c("never", "na")
)
## S3 method for class 'tbl_lazy'
anti_join(
  Х,
  у,
  by = NULL,
  copy = FALSE,
  auto_index = FALSE,
  sql_on = NULL,
  na_matches = c("never", "na")
)
```

#### **Arguments**

x, y A pair of lazy data frames backed by database queries.

by A character vector of variables to join by.

If NULL, the default, \*\_join() will perform a natural join, using all variables in common across x and y. A message lists the variables so that you can check they're correct; suppress the message by supplying by explicitly.

To join by different variables on x and y, use a named vector. For example, by = c("a" = "b") will match x\$a to y\$b.

To join by multiple variables, use a vector with length > 1. For example, by =

join.tbl\_sql 29

c("a","b") will match x\$a to y\$a and x\$b to y\$b. Use a named vector to match different variables in x and y. For example, by = c("a" = "b","c" = "d") will match x\$a to y\$b and x\$c to y\$d.

To perform a cross-join, generating all combinations of x and y, use by = character().

copy If x and y are not from the same data source, and copy is TRUE, then y will be

copied into a temporary table in same database as x. \*\_join() will automatically run ANALYZE on the created table in the hope that this will make you queries as

efficient as possible by giving more data to the query planner.

This allows you to join tables across srcs, but it's potentially expensive operation

so you must opt into it.

suffix If there are non-joined duplicate variables in x and y, these suffixes will be added

to the output to disambiguate them. Should be a character vector of length 2.

auto\_index if copy is TRUE, automatically create indices for the variables in by. This may

speed up the join if there are matching indexes in x.

Other parameters passed onto methods.

sql\_on A custom join predicate as an SQL expression. Usually joins use column equal-

ity, but you can perform more complex queries by supply  $sql_on$  which should be a SQL expression that uses LHS and RHS aliases to refer to the left-hand side

or right-hand side of the join respectively.

na\_matches Should NA (NULL) values match one another? The default, "never", is how

databases usually work. "na" makes the joins behave like the dplyr join func-

tions, merge(), match(), and %in%.

#### Value

Another tbl\_lazy. Use show\_query() to see the generated query, and use collect() to execute the query and return data to R.

```
library(dplyr, warn.conflicts = FALSE)
band_db <- tbl_memdb(dplyr::band_members)</pre>
instrument_db <- tbl_memdb(dplyr::band_instruments)</pre>
band_db %>% left_join(instrument_db) %>% show_query()
# Can join with local data frames by setting copy = TRUE
band_db %>%
  left_join(dplyr::band_instruments, copy = TRUE)
# Unlike R, joins in SQL don't usually match NAs (NULLs)
db \leftarrow memdb_frame(x = c(1, 2, NA))
label <- memdb_frame(x = c(1, NA), label = c("one", "missing"))
db %>% left_join(label, by = "x")
# But you can activate R's usual behaviour with the na_matches argument
db %>% left_join(label, by = "x", na_matches = "na")
# By default, joins are equijoins, but you can use `sql_on` to
# express richer relationships
db1 <- memdb_frame(x = 1:5)
db2 \leftarrow memdb_frame(x = 1:3, y = letters[1:3])
db1 %>% left_join(db2) %>% show_query()
db1 %>% left_join(db2, sql_on = "LHS.x < RHS.x") %>% show_query()
```

30 mutate.tbl\_lazy

memdb\_frame

Create a database table in temporary in-memory database.

#### **Description**

memdb\_frame() works like tibble::tibble(), but instead of creating a new data frame in R, it creates a table in src\_memdb().

# Usage

```
memdb_frame(..., .name = unique_table_name())
tbl_memdb(df, name = deparse(substitute(df)))
src_memdb()
```

# **Arguments**

... <dynamic-dots> A set of name-value pairs. These arguments are processed with rlang::quos() and support unquote via !! and unquote-splice via !!!.

Use := to create columns that start with a dot.

Arguments are evaluated sequentially. You can refer to previously created elements directly or using the .data pronoun. An existing .data pronoun, provided

e.g. inside dplyr::mutate(), is not available.

df Data frame to copy

name, .name Name of table in database: defaults to a random name that's unlikely to conflict

with an existing table.

### **Examples**

```
library(dplyr)
df <- memdb_frame(x = runif(100), y = runif(100))
df %>% arrange(x)
df %>% arrange(x) %>% show_query()

mtcars_db <- tbl_memdb(mtcars)
mtcars_db %>% group_by(cyl) %>% summarise(n = n()) %>% show_query()
```

mutate.tbl\_lazy

Create, modify, and delete columns

# **Description**

These are methods for the dplyr mutate() and transmute() generics. They are translated to computed expressions in the SELECT clause of the SQL query.

```
## S3 method for class 'tbl_lazy'
mutate(.data, ...)
```

pivot\_longer.tbl\_lazy 31

#### **Arguments**

```
    .data A lazy data frame backed by a database query.
    ... <a href="data-masking"></a> Variables, or functions or variables. Use desc() to sort a variable in descending order.
```

#### Value

Another tbl\_lazy. Use show\_query() to see the generated query, and use collect() to execute the query and return data to R.

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = 1:5, y = 5:1)
  db %>%
    mutate(a = (x + y) / 2, b = sqrt(x^2L + y^2L)) %>%
    show_query()

# dbplyr automatically creates subqueries as needed
  db %>%
    mutate(x1 = x + 1, x2 = x1 * 2) %>%
    show_query()
```

```
pivot_longer.tbl_lazy Pivot data from wide to long
```

# **Description**

pivot\_longer() "lengthens" data, increasing the number of rows and decreasing the number of columns. The inverse transformation is 'tidyr::pivot\_wider()]

Learn more in vignette("pivot", "tidyr").

While most functionality is identical there are some differences to pivot\_longer() on local data frames:

- the output is sorted differently/not explicitly,
- the coercion of mixed column types is left to the database,
- values\_ptypes NOT supported.

Note that build\_longer\_spec() and pivot\_longer\_spec() do not work with remote tables.

```
pivot_longer.tbl_lazy(
  data,
  cols,
  names_to = "name",
  names_prefix = NULL,
  names_sep = NULL,
  names_pattern = NULL,
  names_ptypes = list(),
```

32 pivot\_longer.tbl\_lazy

```
names_transform = list(),
names_repair = "check_unique",
values_to = "value",
values_drop_na = FALSE,
values_ptypes,
values_transform = list(),
...
)
```

# Arguments

data A data frame to pivot.

cols Columns to pivot into longer format.

names\_to A string specifying the name of the column to create from the data stored in the

column names of data.

names\_prefix A regular expression used to remove matching text from the start of each vari-

able name.

names\_sep, names\_pattern

If names\_to contains multiple values, these arguments control how the column

name is broken up.

names\_ptypes A list of column name-prototype pairs.

names\_transform, values\_transform

A list of column name-function pairs.

names\_repair What happens if the output has invalid column names?

values\_to A string specifying the name of the column to create from the data stored in cell

values. If names\_to is a character containing the special .value sentinel, this value will be ignored, and the name of the value column will be derived from

part of the existing column names.

values\_drop\_na If TRUE, will drop rows that contain only NAs in the value\_to column.

values\_ptypes Not supported.

... Additional arguments passed on to methods.

#### **Details**

The SQL translation basically works as follows:

- 1. split the specification by its key columns i.e. by variables crammed into the column names.
- 2. for each part in the splitted specification transmute() data into the following columns
- id columns i.e. columns that are not pivotted
- · key columns
- value columns i.e. columns that are pivotted
- 1. combine all the parts with union\_all()

pivot\_wider.tbl\_lazy 33

#### **Examples**

```
# See vignette("pivot") for examples and explanation
# Simplest case where column names are character data
if (require("tidyr", quietly = TRUE)) {
    memdb_frame(
    id = c("a", "b"),
        x = 1:2,
        y = 3:4
    ) %>%
        pivot_longer(-id)
}
```

pivot\_wider.tbl\_lazy Pivot data from long to wide

# **Description**

pivot\_wider() "widens" data, increasing the number of columns and decreasing the number of rows. The inverse transformation is pivot\_longer(). Learn more in vignette("pivot", "tidyr").

### Usage

```
pivot_wider.tbl_lazy(
   data,
   id_cols = NULL,
   names_from = name,
   names_prefix = "",
   names_sep = "_",
   names_glue = NULL,
   names_sort = FALSE,
   names_repair = "check_unique",
   values_from = value,
   values_fill = NULL,
   values_fn = max,
   ...
)
```

# **Arguments**

names\_sep

data A lazy data frame backed by a database query.

id\_cols A set of columns that uniquely identifies each observation.

names\_from, values\_from

A pair of arguments describing which column (or columns) to get the name of the output column (names\_from), and which column (or columns) to get the cell values from (values\_from).

If values\_from contains multiple values, the value will be added to the front of the output column.

names\_prefix String added to the start of every variable name.

If names\_from or values\_from contains multiple variables, this will be used to join their values together into a single string to use as a column name.

34 pivot\_wider.tbl\_lazy

names_glue	Instead of names_sep and names_prefix, you can supply a glue specification that uses the names_from columns (and special .value) to create custom column names.
names_sort	Should the column names be sorted? If FALSE, the default, column names are ordered by first appearance.
names_repair	What happens if the output has invalid column names?
values_fill	Optionally, a (scalar) value that specifies what each value should be filled in with when missing.
values_fn	A function, the default is max(), applied to the value in each cell in the output. In contrast to local data frames it must not be NULL.
	Unused; included for compatibility with generic.

#### **Details**

The big difference to pivot\_wider() for local data frames is that values\_fn must not be NULL. By default it is max() which yields the same results as for local data frames if the combination of id\_cols and value column uniquely identify an observation. Mind that you also do not get a warning if an observation is not uniquely identified.

The translation to SQL code basically works as follows:

- 1. Get unique keys in names\_from column.
- 2. For each key value generate an expression of the form:

```
value_fn(
  CASE WHEN (`names from column` == `key value`)
  THEN (`value column`)
  END
) AS `output column`
```

- 3. Group data by id columns.
- 4. Summarise the grouped data with the expressions from step 2.

```
if (require("tidyr", quietly = TRUE)) {
  memdb_frame(
    id = 1,
    key = c("x", "y"),
    value = 1:2
) %>%
  tidyr::pivot_wider(
    id_cols = id,
    names_from = key,
    values_from = value
)
}
```

pull.tbl\_sql 35

pull.tbl\_sql

Extract a single column

#### **Description**

This is a method for the dplyr pull() generic. It evaluates the query retrieving just the specified column.

# Usage

```
## S3 method for class 'tbl_sql'
pull(.data, var = -1)
```

# **Arguments**

.data

A lazy data frame backed by a database query.

var

A variable specified as:

- a literal variable name
- a positive integer, giving the position counting from the left
- a negative integer, giving the position counting from the right.

The default returns the last column (on the assumption that's the column you've created most recently).

This argument is taken by expression and supports quasiquotation (you can unquote column names and column locations).

# Value

A vector of data.

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = 1:5, y = 5:1)
  db %>%
    mutate(z = x + y * 2) %>%
    pull()
```

remote\_name

Metadata about a remote table

# Description

remote\_name() gives the name remote table, or NULL if it's a query. remote\_query() gives the text of the query, and remote\_query\_plan() the query plan (as computed by the remote database). remote\_src() and remote\_con() give the dplyr source and DBI connection respectively.

36 replace\_na.tbl\_lazy

#### Usage

```
remote_name(x)
remote_src(x)
remote_con(x)
remote_query(x)
remote_query_plan(x)
```

# **Arguments**

Х

Remote table, currently must be a tbl\_sql.

# Value

The value, or NULL if not remote table, or not applicable. For example, computed queries do not have a "name"

# **Examples**

```
mf <- memdb_frame(x = 1:5, y = 5:1, .name = "blorp")
remote_name(mf)
remote_src(mf)
remote_con(mf)
remote_query(mf)

mf2 <- dplyr::filter(mf, x > 3)
remote_name(mf2)
remote_src(mf2)
remote_con(mf2)
remote_query(mf2)
```

replace\_na.tbl\_lazy

Replace NAs with specified values

# Description

This is a method for the tidyr::replace\_na() generic.

# Usage

```
replace_na.tbl_lazy(data, replace = list(), ...)
```

# **Arguments**

data A pair of lazy data frame backed by database queries.

replace A named list of values, with one value for each column that has NA values to be

replaced.

... Unused; included for compatibility with generic.

select.tbl\_lazy 37

#### Value

Another  $tbl_{lazy}$ . Use  $show_{query}()$  to see the generated query, and use collect() to execute the query and return data to R.

# **Examples**

```
if (require("tidyr", quietly = TRUE)) {
   df <- memdb_frame(x = c(1, 2, NA), y = c("a", NA, "b"))
   df %>% replace_na(list(x = 0, y = "unknown"))
}
```

select.tbl\_lazy

Subset, rename, and reorder columns using their names

# Description

These are methods for the dplyr select(), rename(), and relocate() generics. They generate the SELECT clause of the SQL query.

These functions do not support predicate functions, i.e. you can not use where(is.numeric) to select all numeric variables.

### Usage

```
## S3 method for class 'tbl_lazy'
select(.data, ...)
## S3 method for class 'tbl_lazy'
rename(.data, ...)
## S3 method for class 'tbl_lazy'
rename_with(.data, .fn, .cols = everything(), ...)
## S3 method for class 'tbl_lazy'
relocate(.data, ..., .before = NULL, .after = NULL)
```

# **Arguments**

.data	A lazy data frame backed by a database query.
	<pre><data-masking> Variables, or functions or variables. Use desc() to sort a variable in descending order.</data-masking></pre>
.fn	A function used to transform the selected .cols. Should return a character vector the same length as the input.
.cols	<tidy-select> Columns to rename; defaults to all columns.</tidy-select>
.before	<tidy-select> Destination of columns selected by Supplying neither will move columns to the left-hand side; specifying both is an error.</tidy-select>
.after	<tidy-select> Destination of columns selected by Supplying neither will move columns to the left-hand side; specifying both is an error.</tidy-select>

38 summarise.tbl\_lazy

#### **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(x = 1, y = 2, z = 3)
 db %>% select(-y) %>% show_query()
 db %>% relocate(z) %>% show_query()
 db %>% rename(first = x, last = z) %>% show_query()
```

sql

SQL escaping.

# Description

These functions are critical when writing functions that translate R functions to sql functions. Typically a conversion function should escape all its inputs and return an sql object.

#### Usage

```
sql(...)
is.sql(x)
as.sql(x, con)
```

# **Arguments**

con

... Character vectors that will be combined into a single SQL expression.

x Object to coerce

Needed when x is directly suppled from the user so that schema specifications

can be quoted using the correct identifiers.

summarise.tbl\_lazy

Summarise each group to one row

# Description

This is a method for the dplyr summarise() generic. It generates the SELECT clause of the SQL query, and generally needs to be combined with group\_by().

```
## S3 method for class 'tbl_lazy'
summarise(.data, ..., .groups = NULL)
```

tbl.src\_dbi

### **Arguments**

.data A lazy data frame backed by a database query.

... <data-masking> Variables, or functions or variables. Use desc() to sort a variable in descending order.

. groups **Experimental** Grouping structure of the result.

- "drop\_last": dropping the last level of grouping. This was the only supported option before version 1.0.0.
- "drop": All levels of grouping are dropped.
- "keep": Same grouping structure as .data.

When .groups is not specified, it defaults to "drop\_last".

In addition, a message informs you of that choice, unless the result is ungrouped, the option "dplyr.summarise.inform" is set to FALSE, or when summarise() is called from a function in a package.

#### Value

Another  $tbl_{lazy}$ . Use  $show_{query}()$  to see the generated query, and use collect() to execute the query and return data to R.

# **Examples**

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(g = c(1, 1, 1, 2, 2), x = c(4, 3, 6, 9, 2))
db %>%
    summarise(n()) %>%
    show_query()

db %>%
    group_by(g) %>%
    summarise(n()) %>%
    show_query()
```

tbl.src\_dbi

Use dplyr verbs with a remote database table

#### **Description**

All data manipulation on SQL tbls are lazy: they will not actually run the query or retrieve the data unless you ask for it: they all return a new tbl\_dbi object. Use compute() to run the query and save the results in a temporary in the database, or use collect() to retrieve the results to R. You can see the query with show\_query().

```
## S3 method for class 'src_dbi'
tbl(src, from, ...)
```

40 tbl.src\_dbi

### **Arguments**

#### **Details**

For best performance, the database should have an index on the variables that you are grouping by. Use explain() to check that the database is using the indexes that you expect.

There is one verb that is not lazy: do() is eager because it must pull the data into R.

```
library(dplyr)
# Connect to a temporary in-memory SQLite database
con <- DBI::dbConnect(RSQLite::SQLite(), ":memory:")</pre>
# Add some data
copy_to(con, mtcars)
DBI::dbListTables(con)
# To retrieve a single table from a source, use `tbl()`
con %>% tbl("mtcars")
# Use `in_schema()` for fully qualified table names
con %>% tbl(in_schema("temp", "mtcars")) %>% head(1)
# You can also use pass raw SQL if you want a more sophisticated query
con %>% tbl(sql("SELECT * FROM mtcars WHERE cyl = 8"))
# If you just want a temporary in-memory database, use src_memdb()
src2 <- src_memdb()</pre>
# To show off the full features of dplyr's database integration,
# we'll use the Lahman database. lahman_sqlite() takes care of
# creating the database.
if (requireNamespace("Lahman", quietly = TRUE)) {
batting <- copy_to(con, Lahman::Batting)</pre>
batting
# Basic data manipulation verbs work in the same way as with a tibble
batting %>% filter(yearID > 2005, G > 130)
batting %>% select(playerID:lgID)
batting %>% arrange(playerID, desc(yearID))
batting %>% summarise(G = mean(G), n = n())
# There are a few exceptions. For example, databases give integer results
# when dividing one integer by another. Multiply by 1 to fix the problem
batting %>%
  select(playerID:lgID, AB, R, G) %>%
  mutate(
  R_per_game1 = R / G,
```

translate\_sql 41

```
R_per_game2 = R * 1.0 / G
)

# All operations are lazy: they don't do anything until you request the # data, either by `print()`ing it (which shows the first ten rows), # or by `collect()`ing the results locally.
system.time(recent <- filter(batting, yearID > 2010))
system.time(collect(recent))

# You can see the query that dplyr creates with show_query()
batting %>%
  filter(G > 0) %>%
  group_by(playerID) %>%
  summarise(n = n()) %>%
  show_query()
}
```

translate\_sql

Translate an expression to sql

# **Description**

Translate an expression to sql

# Usage

```
translate_sql(
  . . . ,
 con = NULL,
 vars = character(),
 vars_group = NULL,
 vars_order = NULL,
 vars_frame = NULL,
 window = TRUE
)
translate_sql_(
 dots,
 con = NULL,
 vars_group = NULL,
 vars_order = NULL,
 vars_frame = NULL,
 window = TRUE,
  context = list()
)
```

### **Arguments**

..., dots Expressions to translate. translate\_sql() automatically quotes them for you. translate\_sql\_() expects a list of already quoted objects.

con

An optional database connection to control the details of the translation. The default, NULL, generates ANSI SQL.

42 translate\_sql

vars Deprecated. Now call partial\_eval() directly.

vars\_group, vars\_order, vars\_frame

Parameters used in the OVER expression of windowed functions.

window Use FALSE to suppress generation of the OVER statement used for window func-

tions. This is necessary when generating SQL for a grouped summary.

context Use to carry information for special translation cases. For example, MS SQL

needs a different conversion for is.na() in WHERE vs. SELECT clauses. Ex-

pects a list.

#### **Base translation**

The base translator, base\_sql, provides custom mappings for for commonly used base functions including logical (!, &, |), arithmetic (^), and comparison (!=) operators, as well as common summary (mean(), var()) and manipulation functions.

All other functions will be preserved as is. R's infix functions (e.g. %like%) will be converted to their SQL equivalents (e.g. LIKE). You can use this to access SQL string concatenation: || is mapped to OR, but %||% is mapped to ||. To suppress this behaviour, and force errors immediately when dplyr doesn't know how to translate a function it encounters, using set the dplyr.strict\_sql option to TRUE.

You can also use sql() to insert a raw sql string.

### **SQLite translation**

The SQLite variant currently only adds one additional function: a mapping from sd() to the SQL aggregation function STDEV.

```
# Regular maths is translated in a very straightforward way
translate_sql(x + 1)
translate_sql(sin(x) + tan(y))
# Note that all variable names are escaped
translate_sql(like == "x")
# In ANSI SQL: "" quotes variable _names_, '' quotes strings
# Logical operators are converted to their sql equivalents
translate_sql(x < 5 \& !(y >= 5))
# xor() doesn't have a direct SQL equivalent
translate_sql(xor(x, y))
# If is translated into case when
translate_sql(if (x > 5) "big" else "small")
# Infix functions are passed onto SQL with % removed
translate_sql(first %like% "Had%")
translate_sql(first %is% NA)
translate_sql(first %in% c("John", "Roger", "Robert"))
# And be careful if you really want integers
translate_sql(x == 1)
translate_sql(x == 1L)
# If you have an already quoted object, use translate_sql_:
```

window\_order 43

```
x <- quote(y + 1 / sin(t))
translate_sql_(list(x), con = simulate_dbi())

# Windowed translation -------
# Known window functions automatically get OVER()
translate_sql(mpg > mean(mpg))

# Suppress this with window = FALSE
translate_sql(mpg > mean(mpg), window = FALSE)

# vars_group controls partition:
translate_sql(mpg > mean(mpg), vars_group = "cyl")

# and vars_order controls ordering for those functions that need it
translate_sql(cumsum(mpg))
translate_sql(cumsum(mpg), vars_order = "mpg")
```

window\_order

Override window order and frame

# Description

These allow you to override the PARTITION BY and ORDER BY clauses of window functions generated by grouped mutates.

# Usage

```
window_order(.data, ...)
window_frame(.data, from = -Inf, to = Inf)
```

### **Arguments**

```
.data A lazy data frame backed by a database query.... Variables to order byfrom, to Bounds of the frame.
```

```
library(dplyr, warn.conflicts = FALSE)

db <- memdb_frame(g = rep(1:2, each = 5), y = runif(10), z = 1:10)

db %>%
    window_order(y) %>%
    mutate(z = cumsum(y)) %>%
    show_query()

db %>%
    group_by(g) %>%
    window_frame(-3, 0) %>%
    window_order(z) %>%
    mutate(z = sum(x)) %>%
    show_query()
```

# **Index**
